

How to return air in a cold aisle of a micro-module

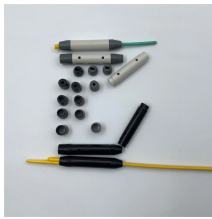

Overview

Traditional open aisle data centers use perimeter PAC (precision air conditioning) or CRAC (computer room air conditioning) units to channel cold air up through a raised floor void via grilles positioned in front of the IT cabinets. Data center operators seeking cost-effective cooling improvements are turning to cold aisle containment as the most retrofit-friendly solution for immediate efficiency gains. An enormous amount of energy is used every day to maintain an acceptable intake temperature to the IT equipment. This has significant disadvantages as there is no separation. Cold aisle containment is one solution to prevent the cold supply air and hot return air from mixing and increasing airflow issues in your aisles. The prevalent design involves directing cold supply air into the contained aisle, either from underneath a raised floor or from the top in constructions. Aisle containment prevents hot exhaust air and cold supply air from mixing, improving the efficiency and consistency of data centre cooling. Cold aisle containment encloses the cold air supply path; hot aisle containment captures and redirects exhaust air before it can re-circulate.
