

Multimode fiber optic transceiver compatibility

Overview

Single-mode (SMF) and multi-mode fiber (MMF) use different core sizes, sources and wavelengths. These differences determine which transceivers work with which fiber and how far signals can travel. Understanding the compatibility constraints prevents costly downtime and troubleshooting. Single-mode. Multimode Fiber (MMF) has a core diameter, typically 50-100 micrometers, has ability to transfer multiple modes of light through the fiber core, uses lower-cost electronics (LED, VCSEL) operates at the 850 nm and 1300 nm wavelength and is used for short distance interconnections (up to 550m). Identical Wavelength Transceivers must support the same wavelength at both ends to transmit data effectively.
